NEW QUESTION: 1
You work in a company which uses SQL Server 2008. You are the administrator of the company database.
Now you are in charge of a SQL Server 2008 instance.
There is a database named DB1 in the instance. You have set the recovery model of DB1 to Full. You
deploy a new process. The process modifies 10,000 records from the Accounts table at 18:00 every day.
Any modification made by the process to the data must be reverted and database keeps online. You must
make sure of this.
So which strategy should you implement?
A. You should implement Database snapshots
B. You should implement Primary filegroup backup
C. You should implement Transaction log backup
D. You should implement Differential backup
Answer: A
Explanation:
A database snapshot is a read-only, static view of a database (called the source database). Each database snapshot is transactionally consistent with the source database at the moment of the snapshot's creation. When you create a database snapshot, the source database will typically have open transactions. Before the snapshot becomes available, the open transactions are rolled back to make the database snapshot transactionally consistent. Clients can query a database snapshot, which makes it useful for writing reports based on the data at the time of snapshot creation. Also, if the source database later becomes damaged, you can revert the source database to the state it was in when the snapshot was created. Reasons to take database snapshots include: Maintaining historical data for report generation. Because a database snapshot provides a static view of a database, a snapshot can extend access to data from a particular point in time. For example, you can create a database snapshot at the end of a given time period (such as a financial quarter) for later reporting. You can then run end-of-period reports on the snapshot. If disk space permits, you can also maintain end-of-period snapshots indefinitely, allowing queries against the results from these periods; for example, to investigate organizational performance. Using a mirror database that you are maintaining for availability purposes to offload reporting. Using database snapshots with database mirroring permits you to make the data on the mirror server accessible for reporting. Additionally, running queries on the mirror database can free up resources on the principal. For more information, see Database Mirroring and Database Snapshots. Safeguarding data against administrative error.
Before doing major updates, such as a bulk update or a schema change, create a database snapshot on the database protects data. If you make a mistake, you can use the snapshot to recover by reverting the database to the snapshot. Reverting is

potentially much faster for this purpose than restoring from a
backup; however, you cannot roll forward afterward.
